EN.601.414/614 Computer Networks

IP Router

Xin Jin

Spring 2019 (MW 3:00-4:15pm in Shaffer 301)

Midterm

Check your grades on blackboard

- > We will go through the midterm next Wednesday
- Some statistics: average 79, median 81, highest grade 100 (congratulations!)
- Come to talk to me during my office hours if you do not do well

Complete the midterm survey

- ➤ It is also available throughout the semester
- ➤ It is anonymous. A private channel to talk to me.
- ➤ Your comments, concerns and questions are very welcome
- ➤ We will summarize and make changes for the second half of the semester

Assignments

Assignment 2 is being graded

➤ Will release the grades this or next week

Assignment 3 will be out next week

- Implementing distributed routing algorithms for IP routers
- ➤ Short tutorial next Monday

Agenda

- IP routers
- Router-assisted congestion control

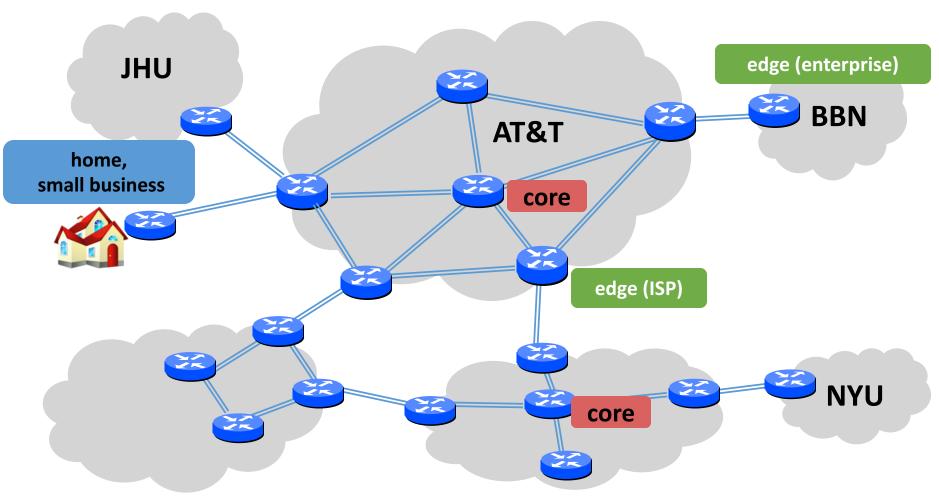

IP routers

- Core building block of the Internet infrastructure
- \$120B+ industry
- Vendors: Cisco, Huawei, Juniper, Nokia (account for >90%)

Router definitions

- Router capacity = N x R
- N = Number of external router "ports"
- R = Speed ("line rate") of a port

Networks and routers

Many types of routers

Core

- ightharpoonup R = 10/40/100 Gbps
- \triangleright NR = O(100) Tbps (Aggregated)

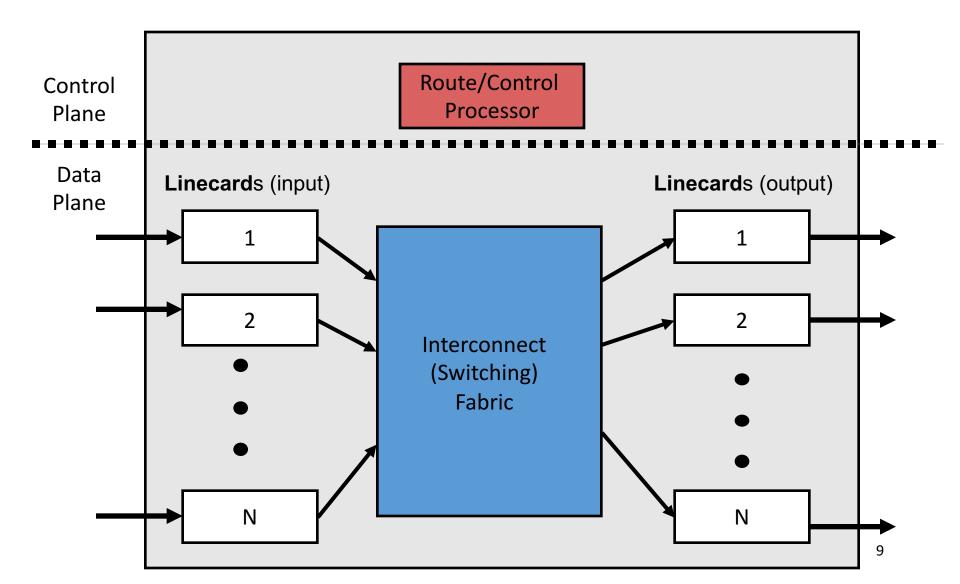

Edge

- R = 1/10/40 Gbps
- \triangleright NR = O(100) Gbps

Small business

- R = 10/100/1000 Mbps
- ➤NR < 10 Gbps

What's inside a router?

What's inside a router?

Linecards

- >Input linecards process packets on their way in
- ➤ Output linecards process packets on way out
- ➤ Input and output for the same port are on the same physical linecard

Interconnect/switching fabric

>Transfers packets from input to output ports

Input linecards

Tasks

- Receive incoming packets (physical layer stuff)
- ➤ Update the IP header
 - TTL, Checksum, Options and Fragment (maybe)
- Lookup the output port for the destination IP address
- ➤ Queue the packet at the switch fabric

Challenge: speed!

- ➤ 100B packets @ 40Gbps → new packet every 20 nano secs!
- Typically implemented with specialized ASICs (network processors)

Looking up the output port

- One entry for each address → 4 billion entries!
- For scalability, addresses are aggregated

Example

- Router with 4 ports
- Destination address range mapping

```
➤ 11 00 00 00 to 11 00 00 11: Port 1
➤ 11 00 01 00 to 11 00 01 11: Port 2
```

➤ 11 00 10 00 to 11 00 11 11: Port 3

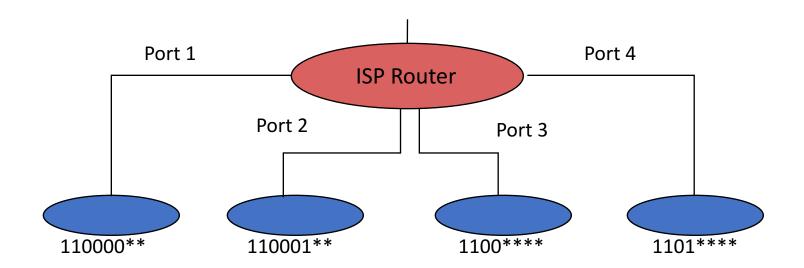

➤ 11 01 00 00 to 11 01 11 11: Port 4

Example

- Router with 4 ports
- Destination address range mapping

```
➤ 11 00 00 00 to 11 00 00 11: Port 1
➤ 11 00 01 00 to 11 00 01 11: Port 2
➤ 11 00 10 00 to 11 00 11 11: Port 3
➤ 11 01 00 00 to 11 01 11 11: Port 4
```

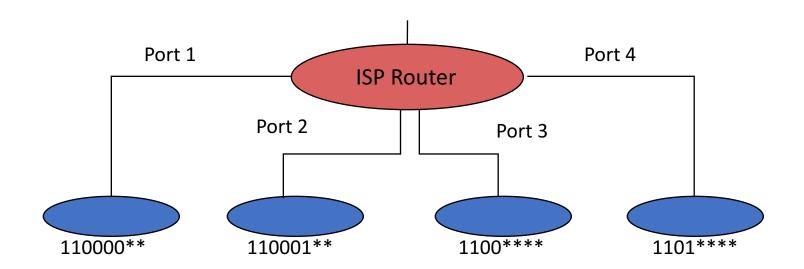

Longest prefix matching

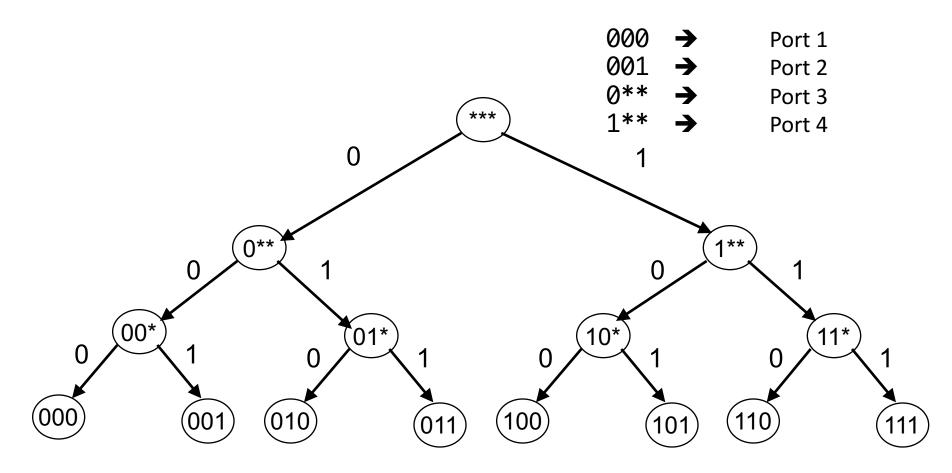

Finding match efficiently

- Testing each entry to find a match scales poorly
 - ➤On average: O(number of entries)
- Leverage tree structure of binary strings
 - ➤ Set up tree-like data structure

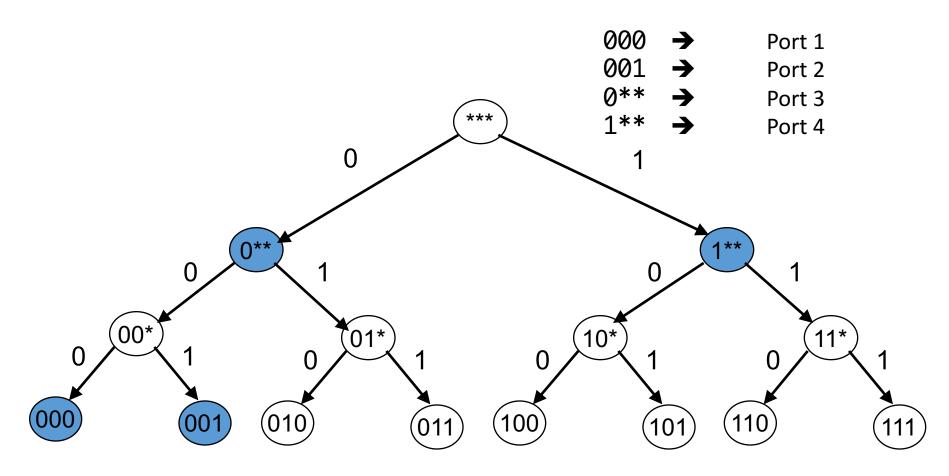

Longest prefix matching

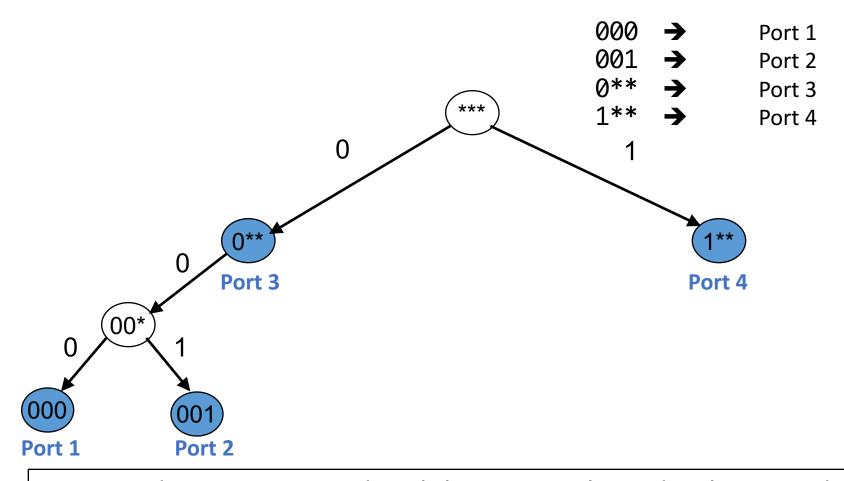

Tree structure

Tree structure

Tree structure

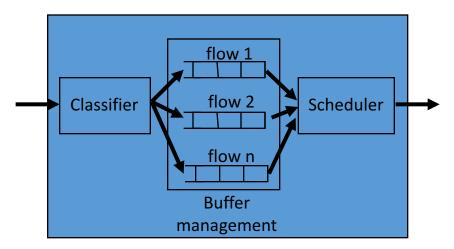

Record port associated with latest match, and only override when it matches another prefix during walk down tree

Input linecards

- Main challenge is processing speeds
- Tasks involved:
 - ➤ Update packet header (easy)
 - >LPM lookup on destination address (harder)
- Mostly implemented with specialized hardware

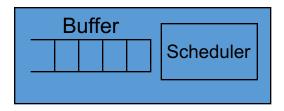

Output linecards

- Packet classification: map packets to flows
- Buffer management: decide when and which packet to drop
- Scheduler: decide when and which packet to transmit
- Some of these functionalities can also be implemented at input linecards

Simplest: FIFO router

- No classification
- Drop-tail buffer management: when buffer is full drop the incoming packet
- First-In-First-Out (FIFO) Scheduling: schedule packets in the same order they arrive

Packet classification

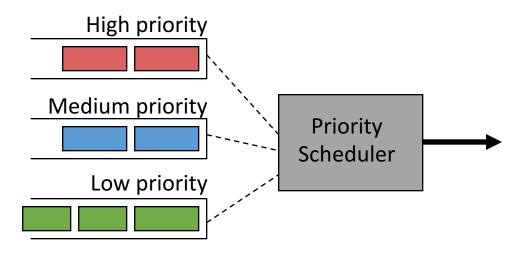

- Classify an IP packet based on a number of fields in the packet header, e.g.,
 - ➤ Source/destination IP address (32 bits)
 - ➤ Source/destination TCP port number (16 bits)
 - Type of service (TOS) byte (8 bits)
 - > Type of protocol (8 bits)
- In general fields are specified by range
 - ➤ Classification requires a multi-dimensional range search!

Scheduler

- One queue per "flow"
- Scheduler decides when and from which queue to send a packet
- Goals of a scheduling algorithm
 - > Fast!
 - ➤ Depend on the policy being implemented (fairness, priority, etc.)

Priority scheduler

 Priority scheduler: packets in the highest priority queue are always served before the packets in lower priority queues

Round-robin scheduler

- Round robin: packets are served from each queue in turn
- Fair queuing (FQ): round-robin for packets of different size
- Weighted fair queueing (WFQ): serve proportional to weight
 - > FQ gives equal weight to each flow

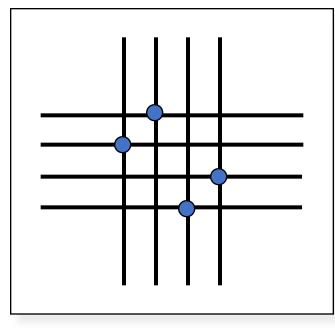

Connecting inputs to outputs: Switching fabric

- Mini-network
- Three primary ways to switch
 - Switching via shared memory
 - ➤ Switching via a bus
 - Switching via an inter-connection network
 - For example, cross-bar

Context

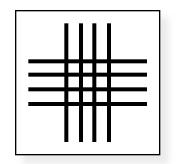

- Crossbar fabric
- Centralized scheduler

Input ports

Output ports

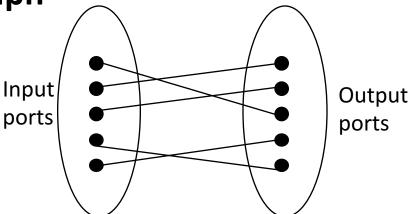

Scheduling

Run links at full capacity, fairness across inputs

Scheduling formulated as finding a matching on a

bipartite graph

 Practical solutions look for a good maximal matching (fast)

Router-assisted Congestion control

Recap: TCP problems

Routers tell endpoints if they're congested

- Misled by non-congestion losses
- Filts up queues leading to high delays
- Short flows complete before discovering available
- AIMD impractical for high speed links
- Saw tooth discovery too choppy for some apps
- Unfair under heterogeneous RTTs
- Tight coupling with reliability mechanisms
- End hosts can cheat

Routers tell endpoints what rate to send at

Routers enforce fair sharing

Could fix many of these with some help from routers!

Router-assisted congestion control

- Three tasks for congestion control
 - ➤ Isolation/fairness
 - **≻**Adjustment
 - ➤ Detecting congestion

Fairness: General approach

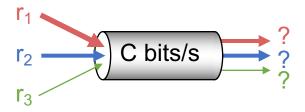

- Routers classify packets into "flows"
 - Let's assume flows are TCP connections
- Each flow has its own FIFO queue in router
- Router services flows in a fair fashion
 - ➤ When line becomes free, take packet from next flow in a fair order
- What does "fair" mean exactly?

Max-Min fairness

 Given set of bandwidth demands r_i and total bandwidth C, max-min bandwidth allocations are:

$$>a_i = \min(f, r_i)$$

 \triangleright where f is the unique value such that $Sum(a_i) = C$

Example

- C = 10; r_1 = 8, r_2 = 6, r_3 = 2; N = 3
- C/3 = $3.33 \rightarrow$
 - r_3 's need is only 2
 - Can service all of r₃
 - \triangleright Remove r_3 from the accounting: $C = C r_3 = 8$; N = 2
- $C/2 = 4 \rightarrow$
 - ➤ Can't service all of r₁ or r₂
 - \triangleright So hold them to the remaining fair share: f = 4

$$f = 4$$
:
min(8, 4) = 4
min(6, 4) = 4
min(2, 4) = 2

Max-Min fairness

 Given set of bandwidth demands r_i and total bandwidth C, max-min bandwidth allocations are:

```
> a_i = \min(f, r_i)
```

- \triangleright where f is the unique value such that $Sum(a_i) = C$
- If you don't get full demand, no one gets more than you
- This is what round-robin service gives if all packets are the same size

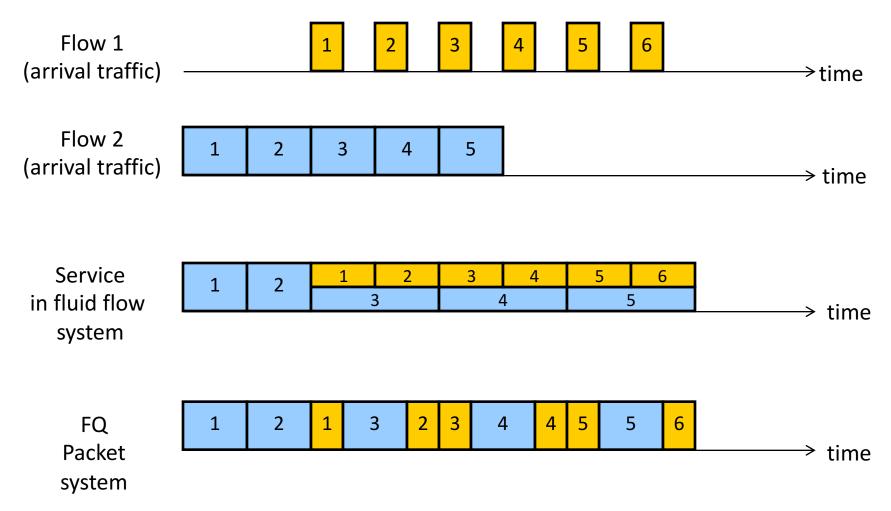

How do we deal with packets of different sizes?

- Mental model: Bit-by-bit round robin ("fluid flow")
- Can you do this in practice?
 - ➤ No, packets cannot be preempted
- But we can approximate it
 - This is what "fair queuing" routers do

Fair Queuing (FQ)

- For each packet, compute the time at which the last bit of a packet would have left the router if flows are served bit-by-bit
- Then serve packets in the increasing order of their deadlines

Example

Fair Queuing (FQ)

- Implementation of round-robin generalized to the case where not all packets are equal sized
- Weighted fair queuing (WFQ): assign different flows different shares
- Today, some form of WFQ implemented in almost all routers
 - ➤ Not the case in the 1980-90s, when CC was being developed
 - ➤ Mostly used to isolate traffic at larger granularities (e.g., per-prefix)

FQ vs. FIFO

FQ advantages:

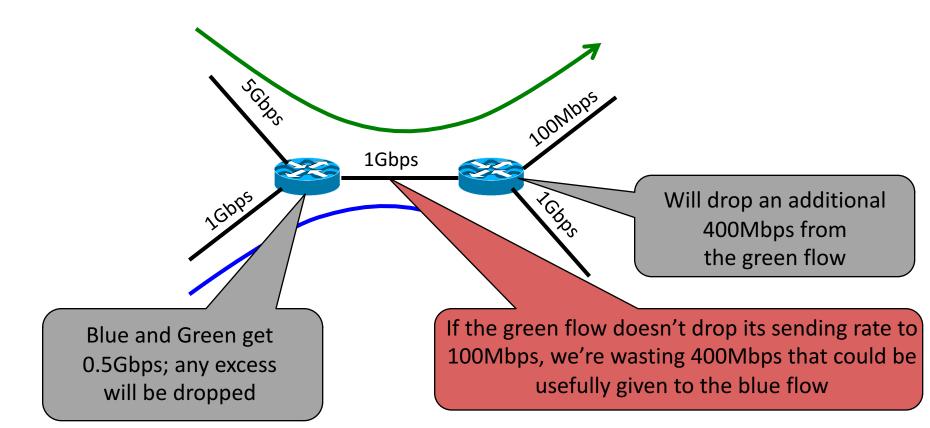

- ➤ Isolation: cheating flows don't benefit
- ➤ Bandwidth share does not depend on RTT
- > Flows can pick any rate adjustment scheme they want

Disadvantages:

➤ More complex than FIFO: per flow queue/state, additional per-packet book-keeping

FQ in the big picture

 FQ does not eliminate congestion → it just manages the congestion

FQ in the big picture

- FQ does not eliminate congestion → it just manages the congestion
 - ➤ Robust to cheating, variations in RTT, details of delay, reordering, retransmission, etc.
- But congestion (and packet drops) still occurs
- We still want end-hosts to discover/adapt to their fair share!
- What would the end-to-end argument say w.r.t. congestion control?

Fairness is a controversial goal

- What if you have 8 flows, and I have 4?
 - ➤ Why should you get twice the bandwidth?
- What if your flow goes over 4 congested hops, and mine only goes over 1?
 - ➤ Why shouldn't you be penalized for using more scarce bandwidth?
- What is a flow anyway?
 - >TCP connection
 - ➤ Source-Destination pair?
 - ➤ Source?

Router-Assisted Congestion Control

- CC has three different tasks:
 - ➤ Isolation/fairness
 - ➤ Rate adjustment
 - ➤ Detecting congestion

Why not let routers tell what rate end hosts should use?

- Packets carry "rate field"
- Routers insert "fair share" f in packet header
- End-hosts set sending rate (or window size) to f
 - ➤ Hopefully (still need some policing of end hosts!)
- This is the basic idea behind the "Rate Control Protocol" (RCP) from Dukkipati et al. '07
 - > Flows react faster

Router-Assisted Congestion Control

CC has three different tasks:

- ➤ Isolation/fairness
- > Rate adjustment
- ➤ Detecting congestion

Explicit Congestion Notification (ECN)

- Single bit in packet header; set by congested routers
 - > If data packet has bit set, then ACK has ECN bit set
- Many options for when routers set the bit
 - >Tradeoff between (link) utilization and (packet) delay
- Congestion semantics can be exactly like that of drop
 - ▶i.e., end-host reacts as though it saw a drop

ECN

Advantages:

- ➤ Don't confuse corruption with congestion; recovery w/ rate adjustment
- ➤ Can serve as an early indicator of congestion to avoid delays
- ➤ Easy (easier) to incrementally deploy
 - Today: defined in RFC 3168 using ToS/DSCP bits in the IP header
 - Common in datacenters

One final proposal: Charge people for congestion!

- Use ECN as congestion markers
- Whenever I get an ECN bit set, I have to pay \$\$
- Now, there's no debate over what a flow is, or what fair is...
- Idea started by Frank Kelly at Cambridge
 - >"Optimal" solution, backed by much math
 - ➤ Great idea: simple, elegant, effective
 - ➤ Unclear that it will impact practice

Summary

- IP routers form the backbone of the Internet
- Aims for speed while providing fairness
- Routers can assist in addressing/mitigating many of TCP's shortcomings

Thanks! Q&A
